INTRODUCTION

Extensive work has been carried out at the Seiler Laboratory to elucidate the nature of the light initiated reaction between XeF_2 and norbornene in acetonitrile. Six major products can be isolated from this reaction, including three which result from reaction with solvent molecules¹. While the molecular composition of these compounds was clearly identified, the exact stereochemistry was not absolutely determined. To unambiguously ascertain this, an x-ray crystal structure of the compound tentatively identified as the cis (or exo-exo) fluoroamide compound was performed. This work was contracted out and accomplished by the Molecular Structure Corporation, College Station, Texas.

EXPERIMENTAL

Data Collection

A colorless needlelike crystal of the compound, having approximate dimensions of $0.08 \times 0.08 \times 0.20$ mm was mounted in a glass capillary with its long axis roughly parallel to the phi axis of the goniometer. Preliminary examination and data collection were performed with $Cu K\alpha$ radiation ($\lambda = 1.54184$ Å) on an Enraf-Nonius CAD4 computer controlled kappa axis diffractometer equipped with a graphite crystal, incident beam monochromator.

Cell constants and an orientation matrix for data collection were obtained from least-squares refinement of the setting angles of 24 reflections in the range $7 < \theta < 20^\circ$, measured using the computer controlled diagonal slit method of centering. The Monoclinic cell parameters and calculated volume are: $a = 10.641(2)$, $b = 9.542(2)$, $c = 18.979(4)$ Å, $\beta = 106.48(2)$, $^\circ$, $V = 1847.9$ Å³. For $Z = 8$ and $F.W. = 171.22$ the calculated density is 1.23 g/cm³. As a check on crystal quality, omega scans

of several intense reflections were measured the width at half-height was 0.30° with a take-off angle of 2.8° , indicating good crystal quality.

From the systematic absences of:

$0k0 \quad k=2n+1$

$h01 \quad l=2n+1$

and from subsequent least-squares refinement, the space group was determined to be $P2-1/c$ (# 14).

The data were collected at a temperature of $23 \pm 1^\circ$ using the $w-\theta$ scan technique. The scan rate varied from 2 to $20^\circ/\text{min}$ (in ω). The variable scan rate allows rapid data collection for intense reflections where a fast scan rate is used and assures good counting statistics for weak reflections where a slow scan rate is used. Data were collected to a maximum 2θ of 120.0° . The scan range (in deg.) was determined as a function of θ to correct for the separation of the $K\alpha$ doublet²; the scan width was calculated as follows:

$$\theta \text{ scan width} = w \text{ scan width} = 0.6 + 0.300 \tan \theta$$

Moving-crystal moving-counter background counts were made by scanning an additional 25% above and below this range. Thus the ratio of peak counting time to background counting time was 2:1. The counter aperture was also adjusted as a function of θ . The horizontal aperture width ranged from 2.0 to 3.7 mm; the vertical aperture was set at 2.0 mm. The diameter of the incident beam collimator was 0.7 mm and the crystal to detector distance was 21 cm. For intense reflections an attenuator was automatically inserted in front of the detector; the attenuator factor was 15.5.

Data Reduction

A total of 3003 reflections were collected, of which 2736 were unique and not systematically absent. As a check on crystal and electronic

stability 3 representative reflections were measured every 41 min. The slope of the least-squares line through a plot of intensity versus time was -35 ± 14 counts/hour which corresponds to a total loss in intensity of 2.3%. A linear decay correction was applied. The correction factors on I ranged from 1.000 to 1.024 with an average of 1.012.

Lorentz and polarization corrections were applied to the data. The linear absorption coefficient is 7.9 cm⁻¹ for Cu K α radiation. No absorption correction was made. An extinction correction was not necessary.

Structure Solution and Refinement

The structure was solved by direct methods. Using 186 reflections (minimum E of 1.36) and 4409 relationships, a total of 32 phase sets were produced. All 24 non-hydrogen atoms were located from an E-map prepared from the phase set with probability statistics: absolute figure of merit = 1.06, residual = 0.18, and psi zero = 1.340. Hydrogen atoms were not included in the calculations. The structure was refined in full-matrix least-squares where the function minimized was $\sum w(|F_O| - |F_C|)^2$ and the weight w is defined as $4F_O^2/\sigma^2 (F_O^2)$.

The standard deviation on intensities, (F_O^2) , is defined as follows

$$\sigma^2(F_O^2) = [S^2 (C + R^2 B) + (pF_O^2)^2] / L_p^2$$

where S is the scan rate, C is the total integrated peak count, R is the ratio of scan time to background counting time, B is the total background count, L_p is the Lorentz-polarization factor, and the parameter p is a factor introduced to downweight intense reflections. Here p was set to 0.070.

Scattering factors were taken from Cromer and Waber³. Anomalous dispersion effects were included in F_C⁴; the values for $\Delta f'$ and $\Delta f''$ were those of Cromer⁵. Only the 346 reflections having intensities greater

than 3.0 times their standard deviation were used in the refinements. The final cycle of refinement included 97 variable parameters and converged (largest parameter shift was 0.1 times its esd) with unweighted and weighted agreement factors of:

$$R1 = \sum | |F_o| - |F_c| | / \sum |F_o| = 0.158$$
$$R2 = \text{SQRT} (\sum w (|F_o| - |F_c|)^2 / \sum w |F_o|^2) = 0.194$$

The standard deviation of an observation of unit weight was 4.13. The highest peak in the final difference Fourier had a height of 0.21 e/ \AA^3 with an estimated error based on ΔF^6 of 0.05. Plots of $\sum w (|F_o| - |F_c|)^2$ versus $|F_o|$, reflection order in data collection, $\sin \theta / \lambda$, and various classes of indices showed no unusual trends.

Since the crystal was quite small and diffracted rather poorly, the data was of less than desirable quality. Many crystals were examined and no better crystal was found. Although there is no doubt as to the basic structure, the poor quality of the data evidences itself in the high standard deviations of individual bond distances and angles and the somewhat anomalous isotropic temperature factors observed for some atoms.

All calculations were performed on linked PDP-11/45-11/60 computers using the Enraf-Nonius Structure Determination Package⁷ as well as private programs of Molecular Structure Corporation⁸.

TABLE II
Intensity Measurements

Instrument:	Enraf-Nonius CAD4 diffractometer
Monochromator:	Graphite crystal, incident beam
Attenuator:	Ni foil, factor 15.5
Take-off angle:	2.8°
Detector aperture:	2.0 to 3.7 mm horizontal 2.0 mm vertical
Crystal-to-detector distance:	21 cm
Scan type:	w-θ
Scan rate:	2 - 20°/min (in omega)
Scan width, deg:	0.6 + 0.300 tan θ
Maximum 2θ:	120.0°
No. of reflections measured:	3003 total, 2736 unique
Corrections:	Lorentz-polarization Linear decay (from 1.000 to 1.024 on I)

TABLE III
Structure Solution and Refinement

Solution:	Direct methods
Hydrogen atoms:	Not included
Refinement:	Full-matrix least-squares
Minimization function:	$\sum w(F_o - F_c)^2$
Least-squares weights:	$4F_o^2/\sigma^2(F_o^2)$
"Ignorance" factor:	0.070
Anomalous dispersion:	All non-hydrogen atoms
Reflections included:	346 with $F_o^2 > 3.0\sigma(F_o^2)$
Parameters refined:	97
Unweighted agreement factor:	0.158
Weighted agreement factor:	0.194
Esd of observation of unit weight:	4.13
Convergence, largest shift:	0.1 σ
Highest peak in final difference Fourier:	0.21 (5) e/ \AA^3
Computer hardware:	Linked PDP-11/45-11/60
Computer software:	Enraf-Nonius SDP and private programs of Molecular Structure Corporation

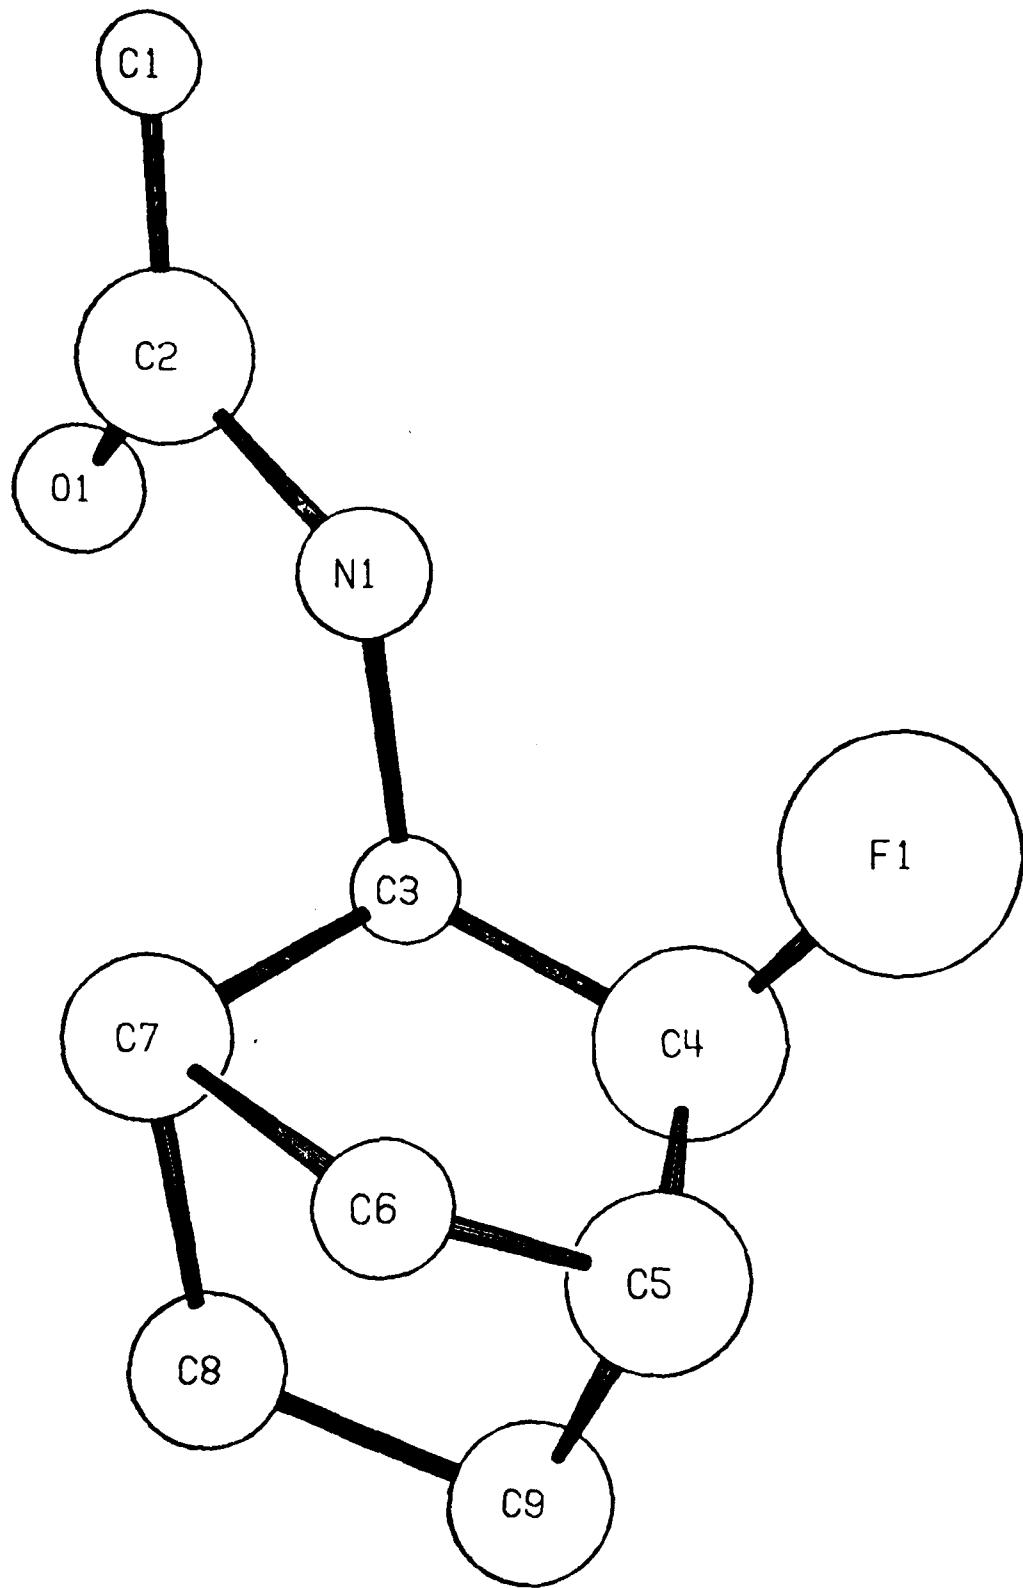

FIGURE 1

RESULTS

Although the diffraction data were less than optimum, the stereochemistry of the molecule was clearly ascertained. A stereoview of the molecule showing 20% probability ellipsoids is shown in Figure 1. The compound is indeed the exo - exo isomer as we had postulated.
